ABSTRACT

Over the recent years, decentralization has been adopted in many health systems. The question however remains of whether local actors do better than the central government. We summarize the main insights from economic theory on the impact of decentralization and its empirical validation. Theory suggests that the decision to decentralize results from a trade-off between its advantages (like its capacity to cater to local tastes) and costs (like inter-regional spillovers). Empirical contributions point that decentralization results in better health outcomes and higher expenditures, resulting in ambiguous consequences on efficiency; equity consequences are controversial and address the relevance of redistribution mechanisms.

Consequências em eficiência e equidade da descentralização na saúde: uma perspetiva económica

RESUMO

Apesar de muitos sistemas de saúde terem optado recentemente pela descentralização, fica por esclarecer se os governos locais têm um melhor desempenho do que os centrais. Este artigo sumariza os principais resultados da teoria económica sobre o impacto da descentralização e a sua validade empírica. A decisão de descentralizar resulta duma arbitragem entre as vantagens, como a adaptação às preferências, e os inconvenientes, como as externalidades inter-regionais. Os estudos empíricos sugerem que a descentralização permite ganhos em saúde mas também despesas maiores, com consequências ambíguas em termos de eficiência, e que as consequências para a equidade, sendo controversas, indicam a relevância dos mecanismos de redistribuição.

Introduction

Over the recent years, decentralization has been one of the main reforms adopted in many health systems. Strong decision power of sub-central governments already existed in Scandinavian counties and in federal states like Canada, Switzerland and Australia¹; the most recent devolution processes have been observed in NHS systems, namely in Spain and Italy (toward regions), and the UK (toward Wales, Scotland, Northern Ireland). In a few words, more delegation to local authorities was expected to improve services through a combination of better knowledge of local needs, preferences and providers' characteristics, higher accountability of policy-makers and efficiency-enhancing competition among jurisdictions.

These expected benefits are however far from obvious and the major question for policy-makers and researchers remains, that is, whether local actors really do better than the central government. Put differently, the issue is whether decentralization allows for the provision of better and equitable health services to all citizens at an acceptable cost. Oates² was the first one to suggest that the decision to decentralize results from a trade-off between its advantages and costs. Whether the benefits actually outweigh the costs – the efficiency issue – is ultimately an empirical question. The literature has mainly focused on overall efficiency by estimating the impact of decentralization on economic growth.^{3,4} Another alternative is to measure the impact of decentralization on sectoral policies.⁵ Decentralization of health policies is relatively recent; the literature is still scarce and often provides contradictory results. We summarize the main insights from economic theory on the impact of decentralization of health policies, and we review empirical studies that have tested some of these theoretical assumptions.

Institutional context

Decentralization in health care can adopt many different forms. Following the typology proposed by Vrangbaek,⁶ our main interest here is in devolution or political decentralization, through which power is “decentralized to lower-level political authorities such as regions or municipalities”. Other forms of decentralization are also possible which are beyond the scope of the present paper. De-concentration and bureaucratization involve transfers between administrative levels and from political to administrative level, respectively (think for example in the Portuguese context, of transfer of competences to Regional Health Authorities). Decentralization also refers to delegation, which involves transferring power to more or less autonomous public organization management (like public enterprises, for example the “hospitals S.A” in Portugal, Foundation Trusts in the UK or public insurance companies in Bismarckian-type health systems). Privatization itself can be considered as a form of decentralization.

Our focus here is thus on the transfer of political authority in the health area from higher to lower levels of government or from national to sub-national levels.⁷ Regional, provincial or municipal elected governments may thus be responsible for

planning, organizing, delivering and financing health services. Multiple arrangements are however possible and devolution has taken many different forms across OECD countries (for a complete mapping of decentralization experiences in Europe, see Bankauskaite et al.⁸). The size of decentralized entities is highly variable, from small counties in Sweden (average population 31,000) to large autonomous regions in Spain (average population 2,444,000). The extent of competences also varies. The central state may keep responsibilities in several domains, for instance the Canadian Federal state defines policies regarding health prevention and promotion, the Swiss Confederation defines the basic health benefit package, and generally all central states impose a series of more or less stringent regulations on quality, supply, coverage, pricing rules or budget allocation. A key issue which differentiates decentralization experiences relates to the funding of health expenditures and financial autonomy. Decentralized governments may have the power to raise taxes, or receive transfers depending on their contribution to fiscal revenues. They may then be free to set the budget allocated to health and its distribution among health sectors. By contrast, sub-central government levels may be financed by transfers based on risk-equalization schemes and benefit from low autonomy in defining tax rates. In the latter case, decentralized governments may thus have the political power to decide about allocation of resources but do not control the amount of available resources for health. Hence the expenditure side is decentralized, but revenue is not.

Fig. 1, extracted from Joumard et al.⁹, nicely describes the degree of decentralization in health in OECD countries (where a 0 score implies that central government takes most of key decisions while a 6 score implies residual competences for the central government). Countries have heterogeneous sub-central governments, with different size, autonomy and responsibilities allocated. The criteria to define this score have been established by Paris et al.¹⁰, using a survey. They include in particular the sub-central governments' authority on setting tax bases and rates, the budget allocation for health and its distribution between health sectors, the financing of different health services and practitioners and the setting of public health objectives. Spain, Canada, Finland, Sweden and Switzerland have higher autonomy of sub-central governments while Portugal is among the countries with the lowest health decentralization.

Note that the decentralization question, the way we pose it (devolution or political decentralization), is more common in NHS-type health systems. These systems have been usually characterized by highly centralized decision-making, with one single insurer/payer and provider (the central state), and little autonomy given to providers. By contrast, health systems based on social insurance schemes have been usually characterized, to various extents, by multiple insurance schemes and some degree of publicly subsidized private provision. Hence, transferring power to local institutions has certainly responded to a demand for more autonomy in more rigid NHS-type health systems.

Spain, Canada and Italy are particularly relevant cases to understand the empirical literature because the consequences of decentralization in health have been more extensively analyzed. The most decentralized country according to

Fig. 1 – Decentralization score for OECD countries (extracted from Joumard et al.⁹).

Joumard et al.⁹ is Spain. The central government provides the general framework and coordinates the health system while Autonomous Communities (AC) provide health care services and are responsible for health planning, organization and management.¹¹ Funds are centrally collected and allocated to regions by means of a block central grant following an unadjusted capitation formula.¹¹ Only Navarra and the Basque Country benefit from fiscal authority.

By contrast, the Canadian Confederation, composed of 10 provinces and 3 territories, has been decentralized since the 19th century.¹² Health funding, administration and delivering are competences of provinces, which also define physician financing rules and hospital global budgets. However health promotion, prevention and provision to specific groups are Federal competencies. Provinces are responsible for funding health care expenditures, based on provincial taxes and transfers from the central government. Transfers depend themselves on taxes collected at provincial level; an equalization program was however implemented to avoid strong differences in transfers related to discrepancies in provinces' revenue-generating potential.¹³

Finally, the 20 Italian regions also control health care provision, although general objectives (like the detailed list of services to be provided) and main principles of the health system are defined at the central level. Regions can develop regional health plans, allocate resources and collect revenues freely, like setting user charges for drugs prescriptions or reimburse rates for drugs and services not covered at national level. Regional authorities also enjoy financial autonomy in taxation; in practice, regional health expenditures are financed at 36.7% by regional taxes.¹⁴ Additionally, regional health expenditures are financed by transfers from the central state (57.3% of expenditures), essentially from a so-called National equalizing fund. This fund is based on the idea that all regions must achieve a minimum level of expenditures, so that transfers top up regions' own revenue in case it is unable to fund this minimum level.

Theoretical background

The debate on the relative merits of policy decentralization dates back to Tiebout,¹⁵ who put forward a very optimistic

argument for the optimality of local public good provision, based on an analogy between competitive markets and competing jurisdictions. Oates,² in contrast, suggests that decentralization results from a trade-off between its advantages and costs. According to Oates, the advantage of decentralization lies in its capacity to cater to local tastes, be it because of better information or simply because the central government cannot differentiate public good provision. The cost of decentralization stems essentially from the presence of inter-regional spillovers. For instance, better health prevention in one municipality benefits its neighbors. However, if health prevention is decentralized, each municipality fails to take into account the benefit of its investment in other municipalities, and is therefore likely to invest sub-optimally, leading to under-provision and/or low quality of health services. While Oates' argument that a central government is unable to differentiate the provision of local public goods according to local preferences has been challenged since, his main intuition that the decision to decentralize rests on a fundamental trade-off between costs and advantages remains. One of the main costs of decentralization which has been analyzed in the literature is the failure to exploit economies of scale.¹⁶ For instance, collective purchasing of resources (drugs, medical devices, equipments, etc.) or collective administration of health services may display decreasing average costs and be thus more efficiently provided at a centralized level.

The inter-regional spillovers at the heart of Oates's argument, referred here-above, are of the horizontal type (that is, between sub-central governments of the same level). Another sort of spillovers which may create inefficiencies under decentralization is the vertical ones between local and central governments. These occur if one government level's policy decisions have an impact in the policy outcomes of the other level. These phenomena are highly plausible in the health care sector. If, for example, sub-central governments are responsible for some public health prevention programs and the central state delivers health care, local policies likely affect services use and costs at the central level. Unless sub-central governments are rewarded for their actions, they have little incentives to provide an optimal value of prevention, whose benefits are fully enjoyed by the central state.

Recently, the literature has put forward political economy arguments in favor of decentralization. For instance, it may be that the voters, who are imperfectly informed about the economy, use the policies put in place by the neighboring politicians to impose discipline on their own local representative. In such a world of opportunistic policy makers, decentralization may be a strong mechanism to prevent corruption or promote provision of public services.¹⁷ Another argument is that decentralization forces local jurisdictions to compete for mobile resources (for instance, labor or capital) and puts a downward pressure on taxation, thus prompting a more efficient use of scarce resources (see Wilson¹⁸ for a survey of the tax competition literature). Besley and Smart¹⁹ show that this need not be the case, since higher discipline of local politicians comes at the cost of a worse selection. Indeed, it is only when an opportunistic politician misbehaves that the voters are given the chance to oust her from power and replace her with a potentially benevolent politician. Political accountability results from a trade-off between these two mechanisms (discipline and selection), and further decentralization has opposite effects in both.

What can be said about the likelihood of local governments being captured by special interests? Bardhan and Mookherjee²⁰ show that there is no theoretical reason to suppose that local governments are more prone to this than central ones. They put forward a theoretical model of probabilistic voting where capture by special interests results from a combination of voter awareness, interest group cohesiveness, electoral uncertainty and competition, district heterogeneity and the electoral system. Their main conclusion is that the extent of capture at the local level is most likely context-specific and needs to be assessed empirically.

A few authors have looked at the applicability of these arguments to the specific case of health decentralization. Levaggi and Smith²¹ claim that sub-central governments are better informed about the constraints of local supply and about variations in demand. Variations in demand are obviously related first to differences in local needs, for instance regions experience discrepancies in the prevalence of diseases, in behavioral and non-behavioral risk factors (including in particular ageing or social determinants), perhaps also in the effectiveness of specific interventions. Hence priorities are likely to differ according to burden of disease or cost-effectiveness criteria. Also local preferences shape variations in demand, leading to different priorities and resource allocation criteria. We may think that some regions have a higher concern for inequalities in health and social determinants, while others put a greater emphasis on provider choice and responsiveness to patients' preferences. These differences in needs and preferences are very clear if we compare European countries. Discrepancies in local supply are related to the availability and density of physicians, nurses, equipments, but also to differences in local prices and practices. Central governments have tried to account for these differences in financing sub-central governments, through more or less sophisticated risk-adjustment schemes, but may not be able to address these issues to locally adjusted planning or organization. Sub-central governments may be better equipped to respond to local preferences and priorities, to coordinate providers' actions and to identify the sources of inefficiency. Hence, decentralization is expected to

enhance quality and responsiveness of care while reducing costs; this theoretical view is at the origin of most decentralization processes.

As regards the potential incentives that favor efficiency and/or quality in health care provision, both the tax competition and the yardstick competition mechanisms are likely to arise in health policies, thus leading sub-central governments to compete with each other to provide high-quality services at low user charges or financed through lower taxes. First, better and more efficient services contribute to attract mobile citizens, hence increase sub-central governments' economic activity and fiscal revenues. Second, competition occurs through citizens benchmarking their demands on the basis of neighbor sub-central governments' performance.²² If sub-central governments are politically accountable, a local politician providing poorer services than his neighbors' counterparts would likely fail re-election. In a few words, efficient provision contributes to attractiveness and citizens' satisfaction.

It is a well-known fact that decentralization may hamper redistribution (see, Cremer et al.²³ for a survey of the literature), when taxes are locally collected. Areas with high health needs are in general the poorer ones (there is large evidence of the relationship between poverty and poor health status, see Marmot Review²⁴); under fiscal decentralization, underprivileged areas capture lower resources from taxation and benefit from a lower capacity to invest in high-quality services and efficient provision. Decentralization then produces differences in the quality and availability of services, charges and outcomes. Increasing inequity is one of the major threats of decentralization, even if good risk-sharing agreements potentially mitigate this effect. In other words, the viability of decentralization depends on the existence of solidarity mechanisms between decentralized authorities.

The reverse is also possible, i.e., sub-central governments only competing on high-quality services, leading to over-provision of services and high health expenditures (*race to the top*). This situation is more likely to occur when fiscal decentralization is low and sub-central governments face soft budget constraints. This may be the case, for example, if the central government systematically bails out sub-central governments which are excessively indebted or if transfers to sub-central governments are based on past expenditures.

This brings us to the fundamental question of the funding of local public goods. Indeed, various arrangements are possible regarding the degree of decentralization of both the expenditure and the revenue functions.²⁵ A considerable share of local government funding comes from central government transfers. These transfer schemes must be carefully designed and rest on clear rules (depend on variables which are not easy for local governments to manipulate) so as to avoid moral hazard leading to excess expenditures. Indeed, as the central government is unable to distinguish the sources of high spending between higher needs and inefficiencies, sub-central governments have an incentive to hide their true needs to obtain higher financing from the central authority.

To sum up, the theoretical literature does not provide a definitive answer about the impact of decentralization on health policies. The high concern in many countries for equity

Table 1 – Literature review: impact of decentralization.

1st author	Country	Objective	Period of the data	Decentralization indicator	Main results
Zhong ⁽²⁰¹⁰⁾	Canada	Impact of the introduction of a higher degree of decentralization on equity in health care utilization	1994/95 1998/99 2000/01	Introduction of Health and Social Transfer in 1996/97, i.e., larger block funding to provinces	Most inequity in health care use is explained by variations within provinces. An increase in decentralization lead to lower overall and within-province inequity in GP and hospital services and lower between-province variation in GP, hospital and specialist services
Scheffler ^(2006 S.)	USA/California	Impact of higher decentralization of mental health care services on uninsured health spending	1989–2000	Decentralization of health, mental health, and social services (greater financial flexibility and responsibility) from the California state to counties (program realignment introduced the ability to transfer funds between programs – mental health, social services and general health)	County spending on mental health services decreased after program realignment. Counties with above median health revenues are less likely to make a transfer to another program. With realignment, counties showed the same level of commitment and support with mental health services, since diverted funds went mainly to mental health services within the realignment programs package
Jiménez-Rubio ^(2011A)	20 OECD countries	Impact of decentralization on health status (infant mortality)	1970–2001	Decentralization measured as: (i) Share of autonomous tax revenue of SCG over the CG tax revenue. (ii) Share of total (autonomous or not) SCG tax over the total revenue	Negative and significant relationship between fiscal decentralization and infant mortality, if a substantial degree of autonomy in the sources of revenue is devolved to sub-central governments
Prieto ⁽²⁰¹²⁾	Spain	Estimate determinants of regional health care expenditure, in particular the degree of regional autonomy	1992–2005	Regions clustered according to the degree of autonomy: (i) Expenditure and high fiscal autonomy. (ii) Expenditure and low fiscal autonomy. (iii) No autonomy	GDP/capita has more influence on HCE in regions with higher tax autonomy, maybe due to equalization efforts of Spanish NHS. Decentralization without inequality is possible with fiscal equalization. If high differences in wealth and weak equalization among regions, decentralization leads to inequality
Bordignon ^(2009 B.)	Italy	Impact of regions' bailout expectations on funding by CG; impact of regions' bailout expectations on HCE (mid-90s), determinants of regions' bailout expectations	1990–1999	Regions' bailout expectations based on external constraints in the mid-90s: countries' evaluation for entering the EURO (1997), index of public budget tightness, Maastricht rules (1994)	HCE is influenced by regional financing, which is in turn influenced by bailout expectations from the CG. Lower expectations of bailing out generate a stronger link between ex-ante financing and regional HCE. Richer and more autonomous regions have lower expectations of CG intervention, hence they are more financially responsible. The CG is also more prone to cut financing to regions under lower bailout expectations because the commitment to cut HCE will be taken seriously
Fredriksson ^(2008 F.)	Sweden	Estimate cross-counties differences in supporting the "Patient Choice Recommendation", i.e., counties' willingness to favor or not the patient's choice of specialist	2001–2005	Recommendation by the CG can be more or less supported by counties, which have large competences in the health sector	High variation on support for the Patient Choice Recommendation among county councils. Ability to choose healthcare provider varies according to county, creating inequalities in access to care

Table 1 (Continued)

1st author	Country	Objective	Period of the data	Decentralization indicator	Main results
López-Casasnovas ^(2007 L.-C.)	110 regions in 8 OECD countries	Measure the determinants of HCE accounting for regional effects	1997	No indicator of decentralization but account for possible regional differences in HCE	An increase on the percentage of people with more than 65 years and in the percentage of public health expenditures increases HCE. Between countries variability of expenditures is smaller than within country variations. Income elasticity of HCE is low and increases with variation in HCE
Costa-Font ^(2007 C.-F.)	Spain	Measure spatial spillovers in HCE (inter-jurisdiction interactions in defining HCE)	2003	Compare regions with (i) fiscal and political autonomy (Navarra and Basque country); (ii) political autonomy (Catalonia, Galicia, Andalucía, Canarias and Valencia); (iii) no autonomy	Evidence of spatial correlation. Higher HCE when regions have higher political decentralization and even higher if they have also fiscal decentralization. Higher HCE if region and CG are ruled by the same party
Costa-i-Font ^(2005 C.-i.-F.)	Spain	Measure income-related intra-regional inequalities in self-reported health, and its relation with the degree of decentralization	1997	Compare regions with (i) fiscal and political autonomy (Navarra and Basque country); (ii) political autonomy (Catalonia, Galicia, Andalucía, Canarias and Valencia); (iii) no autonomy	Overall inequality is low. Devolution does not favor inter-region inequality. By contrast devolution seems to favor pro-equity policies: inequality is the highest in regions without autonomy (INSALUD)
Crivelli ^(2006 C.)	Switzerland	Measure determinants of public HCE accounting for regional (cantons) effects	1996–2001	No indicator of decentralization but account for possible regional differences in HCE	Differences in HCE related to usual factors but in particular to physician density. Strong differences in HCE across cantons explained in part by differences in supply
Costa-Font ^(2009 C.-F.)	Spain	Impact of decentralization on HCE, interdependency between neighbor municipalities and measure income effect at regional level	1995–2002	Indicators of decentralization degree and its evolution across time, toward current situation: (i) fiscal and political autonomy (Navarra and Basque country); (ii) political autonomy (Catalonia, Galicia, Andalucía, Canarias, Valencia); (iii) no autonomy	Political decentralization increases HCE in the short term but produces cost savings in the long run (sunk cost of decentralization and experience effects). Higher expenditures are related to higher fiscal autonomy. Existence of spatial correlation. Low impact of income on HCE, hence decentralization is not associated to strong regional inequalities
Cantarero ^(2005 C.)	Spain	Measure determinants of public HCE accounting for regional effects	1993–1999	Compare regions with (i) fiscal and political autonomy (Navarra and Basque country); (ii) political autonomy (Catalonia, Galicia, Andalucía, Canarias, Valencia); (iii) no autonomy	Regional income and supply have low impact on HCE, while ageing is more relevant. Hence lower income-related inequality is expected
Jiménez-Rubio ⁽²⁰¹¹⁾	Canada	Impact of fiscal decentralization on health outcomes (infant mortality)	1979–1995	Fiscal decentralization is measured as the proportion of sub-national health spending over total health expenditure	Significant and substantially lower infant mortality related to higher fiscal decentralization (1% increase in fiscal decentralization decreases infant mortality by 10%)
Giannoni ⁽²⁰⁰²⁾	Italy	Measure determinants of HCE accounting for regional effects, and impact of 1992 cost-containment reforms	1980–1995	No indicator of decentralization but account for possible regional differences in HCE	Strong impact of regional income on HCE and relevant area cluster differences. Cost-containment reforms did not alter most regional differences in HCE and worsened the situation of some regions below the average

Table 1 (Continued)

1st author	Country	Objective	Period of the data	Decentralization indicator	Main results
Cantarero (2008 C.)	Spain	Impact of fiscal decentralization on health outcomes (infant mortality and life expectancy)	1992-2003	Fiscal decentralization is measured as the proportion of sub-national health spending over total health expenditure	Decentralization significantly reduces infant mortality and increases life expectancy
Di Matteo (1998)	Canada	Measure determinants of HCE accounting for regional (provinces) effects	1965-1991	No indicator of decentralization but account for possible regional differences in HCE	HCE highly related to per capita income (but elasticity below 1), ageing and federal transfers. Reflects provincial HCE reflects transfers from CG which however do not correct regional income discrepancies
Jiménez-Rubio (2008 J.-R.)	Canada	Measure income-related inequalities in health and health care use across regions (provinces)	2001	No indicator of decentralization but measure regional differences in inequalities	Health care use inequalities are driven by between-provinces variation. Inequalities in health are mostly driven by within-provinces variation. Different results for health and health care inequalities seem to suggest other health determinants rather than health care access are essential to explain inequalities

HCE, health care expenditures; CG, central government; SCG, sub-central government; GP, general practice; AC, autonomous communities.

in health is a major argument against decentralization, unless strong solidarity mechanisms are put in place. The contradictory expectations about efficiency require careful empirical validation. In these times of adverse economic circumstances, efficiency is more than ever a major issue in decision-making, and strong evidence is necessary before advocating for decentralization in health.

Empirical evidence

In order to get an exhaustive overview on empirical evidence, we performed a systematic literature review. We conducted a computerized literature search in PubMed (National Center for Biotechnology Information, Bethesda, Maryland) and Google Scholar, supplemented by a search of quoted references. Text keywords used in the search included decentralization, federalism, health, health care, equity, and efficiency. We restricted our analysis to those performed in OECD countries to allow for relevant comparisons, that is, in a comparable context. We only included empirical studies about the impact of decentralization, hence excluding theoretical studies, studies about legislation or about political or organizational aspects of decentralization, editorials and literature reviews. The search was limited to English-language articles published from 1995 to July 2012, when decentralization in health has become a relevant and applied policy option in OECD countries. Our search allowed collecting 17 papers, whose main characteristics and results are displayed in Table 1. Studies were divided according to distinct analyzes, based on the most relevant decentralization outcomes, namely inequalities in health and health care, health expenditures and health outcomes.

Inequality in health and health care use

The consequences of decentralization on inequality were the main issue analyzed by Zhong¹³, Jiménez-Rubio et al.¹, Costa-Font²⁶ and Frederiksson and Winblad²⁷. Zhong¹³ found that in Canada inequalities in health care use (overall, within provinces and between provinces) decreased after decentralization. Most inequality was explained by within-provinces variation, while between-provinces variations did not much contribute to inequality.¹³ By contrast, Jiménez-Rubio et al.¹ also using data from Canadian provinces observed that income-related inequalities in health care use resulted from between-provinces variations while income-related inequalities in health were related to within-region variations. While Zhong¹³ used an overall inequity measure, Jiménez-Rubio et al.¹ used an income-related one, which possibly explains the discrepant results. The results by Jiménez-Rubio et al.¹ certainly question the equalization scheme across provinces; the redistribution of funds from richer to poorer provinces does not seem to avoid inequity in health care use related to between-province variations (for example, health care use is lower in Quebec that has a lower-than-average income per capita). As the author emphasizes, advocates of decentralization would however consider these differences as related to different preferences, hence legitimate. Income-related inequity in health was mostly related to differences between rich and poor people within provinces, here questioning

the efforts by provinces to reduce inequalities (would a central government be more committed to reduce inequity in health?).

For Spain, Costa-i-Font²⁶ found a small overall, within and between regions income-related inequality in health, although somewhat higher in regions with lower autonomy. The author explains this difference by the greater role of the private sector in those regions. He also emphasizes that decentralization may have favored equity due to a high commitment of regions to achieve this objective, which corresponds to a high citizens' concern. Finally, Fredriksson and Winblad²⁷ studied a specific reform toward more provider choice in Sweden, where health care use is highly decentralized at the county level. The author showed that while some counties supported the reform through favoring choice, others implemented administrative barriers against it. Therefore, autonomy on decision making (regarding provider choice) resulted on inequalities between people living in different Swedish counties.

Health expenditures

Inequality related to decentralization was also observed indirectly, through examining the impact of regional GDP per capita on health care expenditures. Indeed, a greater impact of regional income on health care expenditure would mean that richer regions spend significantly more on health than poor ones, hence creating inequalities in health care use. Although all studies using regional data conclude that health care expenditures do not vary much with income (the elasticity with respect to income is below one), results are contrasted and vary between countries. For Spain, Prieto and Lago-Peñas²⁸ found a positive relation between income and public health expenditures only in regions with higher fiscal autonomy. Regions without fiscal autonomy benefitted from national equalization efforts and therefore managed to achieve high levels of health care expenditures despite of lower income. The low impact of income on health care expenditures in Spain was confirmed by Cantarero, Costa-i-Font and Moscone.^{29,11} The same conclusion could be drawn for Canada,²¹ although the impact of income on health expenditures was greater than in Spain. Using a specific indicator, Di Matteo and Di Matteo³⁰ showed the positive impact of federal transfers on health care expenditure. That is, federal transfers certainly reduce the impact of regional income on expenditures but do not fully correct regional income discrepancies. The picture is somewhat different in Italy, where regional income had a strong impact on health care expenditures.³¹ The authors showed also that cost-containment measures have not altered cross-regional differences in health care expenditures and have even worsened them in some cases. For Switzerland, Crivelli et al.³² observed a large impact of physician supply, which is highly variable across regions, on health care expenditures. Hence cross-regional differences in health care supply may also be a source of inequality across regions. Finally, using data from 110 regions of 8 OECD countries, Lopez-Casasnovas and Saez³³ showed a low elasticity of health care expenditure with respect to income. However, the impact of income was higher across regions in countries with higher inter-regional income

inequalities, leading in turn to higher discrepancies in health care expenditures.

Scheffler and Smith³⁴, Costa-i-Font and Moscone¹¹, Costa-i-Font and Pons-Novell²² addressed the impact of decentralization on health expenditures, while Bordignon and Turati³⁵ examined the impact of the interaction between central and sub-central governments. Scheffler and Smith³⁴ showed for California that spending on uninsured patients decreased with the higher counties' autonomy in allocating funds across health and social programs. Costa-Font and Pons-Novell²² observed that Spanish regions with both political and fiscal autonomy had higher health expenditures as compared to regions without autonomy or with political autonomy only. Costa-i-Font and Moscone¹¹ observed however that decentralization increased expenditures only in the short run, producing savings in the long run. They argued that firstly decentralization increased health care costs due to sunk costs; then this effect was minimized in the long run by an experience curve, that is, learning-by-doing allowed reducing costs. Regarding assumptions from economic theory, Costa-i-Font and Moscone¹¹ also showed the existence of spatial correlation of health care expenditures between neighbor jurisdictions, sustaining the assumption of horizontal spillovers. This result may hence be due to competition between neighbor jurisdictions to increase attractiveness or due to politicians being judged based on the neighbor counterparts' actions.

Finally, Bordignon and Turati³⁵ used 1990s Italian adjustment process imposed by an external entity (the European Union) to understand the role of expectations and the strategic interactions between the central state and regions, using data on health care expenditures. Regions expecting that the central government will intervene in case of debt softened their budget constraints and the relationship between the funding they receive from the central government and health expenditures was lower. By contrast, during external adjustment, the central government was perceived as more stringent and the link between funding and expenditures became stronger. And the central government was also more prone to cut funding to regions because it knew its commitment not to bailout would be taken more seriously. Interestingly, authors showed that more autonomy lead to more financially responsible policies because expectations of bailout were low. This paper thus emphasized that transfer mechanisms, which are always present in decentralized countries, created incentives that may be more or less detrimental for efficiency depending on how they are designed and put in practice.

Health results

Results about the impact of decentralization on health outcomes are scarce but consistent across studies. Jiménez-Rubio^{12,36} and Cantarero and Pascual³⁷ agree on identifying a positive relationship between fiscal decentralization and health results, measured through infant mortality. Cantarero and Pascual³⁷ used an alternative measure of health status (life expectancy) which confirmed the positive contribution of decentralization to health status.

Conclusion

Although the economics literature has largely discussed the impact of decentralization, empirical results remain scarce, in particular regarding decentralization in health. Nevertheless, decentralization of health policies and funding has been largely implemented in various countries and is generally considered as a relevant option to improve efficiency in health care.⁷

Our review of the literature allows draw preliminary conclusions, based on relatively recent decentralization experiences, in particular in Canada, Italy, Spain and Switzerland. First and foremost, devolution of political (and fiscal) authority to sub-government levels seems to increase health care expenditures but also improve health outcomes, mainly measured through infant mortality rate. According to economic theory, decentralization may foster competition between jurisdictions to increase attractiveness, and increase pressure on local governments because citizens evaluate their performance based on neighbor counterparts' actions. The empirical literature suggests that enhanced competition prompts local decision-makers to increase health care expenditures (*race to the top*) and not the reverse in order to decrease taxes (*race to the bottom*), with a favorable impact on health. The case of Spain is particularly enlightening, which shows that the increase in health care expenditures has been the highest in regions with fiscal autonomy. This result may reflect the high people's demand for high-quality health services, and the higher responsiveness of local authorities to this preference. The higher health care expenditures under decentralization may however reflect also higher costs, related for instance to duplication of inputs (two neighbor regions offering similar services which could be shared), diseconomies of scale, or the sunk costs associated to implementation of a local health provision scheme. To some extent, adverse incentives may play some role if sub-central governments are not fully financially responsible for their expenditures. In particular, moral hazard may exist if sub-central governments expect their debts being covered by the central state (bailout) or if their budget depends more largely from transfers from the central state. In a few words, decentralization does not appear at first sight as a means to control or reduce health care expenditures, but as an incentive to provide better and possibly more expensive services. The efficiency consequences are thus ambiguous, as it is unclear whether additional benefits – measured through a very reduced number of indicators – are worth additional costs.

Regarding equity, empirical results are ambiguous and certainly related to the specific countries' context. Inequity in health and health care is low in Spain, where health expenditures are also poorly related to the region GDP/capita. Additionally, inequity in health care seems to be lower in more autonomous regions, so that decentralization may have favored equity. In Canada, income-related inequity in health care is related to between-provinces inequalities. In Italy and Switzerland, there is a strong relationship between regions (resp. cantons) income and health care expenditures, resulting in a large heterogeneity in health care expenditures. These results may certainly be related to lower equalizing

mechanisms in these two countries coupled with a higher fiscal autonomy. Note also that different decisions across regions, namely about physicians or equipment supply, also potentially create differences/inequity in health care delivery.

To conclude, solidarity mechanisms across sub-central authorities are relevant to avoid the emergence of large inequalities across regions in health care delivery and expenditures. However, redistribution of funds also reduces jurisdictions' financial responsibility, with possible detrimental consequences on expenditures and ambiguous consequences on efficiency. This last aspect is of particular importance if jurisdictions compete with each other for providing high-quality services and not through lowering tax rates.

Funding

This investigation was funded by the Fundação para a Ciência e a Tecnologia through the project PTDC/EGE-ECO/104094/2008.

Conflicts of interest

The authors declare that there are no conflicts of interests.
